\*Change; \*Farmers; \*Income; Vocational Education

#### **ABSTRACT**

This report compares several farm characteristics of the mid-1980s with those of a decade earlier to document the real amount of change in the farm sector. Farms are stratified into five groups based on their farm income: rural residence, small family, family, large family, and very large. Sources and levels of farm operator income and wealth are first considered. Land ownership and tenure patterns are examined. Some variables are studied that can be measured to indicate variations in farm organization: farming enterprises, technology, yields, and intensity of resource use. An examination follows of changes in the degree of concentration of production and land used for producing specific agricultural commodities. The analysis uses Gini index-Lorenz curves and distribution curves. Census of Agriculture data for 1974, 1978, and 1982 are used to trace change in several variables that are important measures of the structure of the farm sector. Structural change variables are examined in both nominal and real terms. A final section describes further the five sales classes. Regions are compared with the national average. The bisic structural characteristics addressed are farm numbers and size, asset value, sales, tenure, organization, off-farm work, age, and expenses. Forty-nine tables supplement the text, and a short list of other agricultural reports is included. (YLB)

The U.S. Farm Sector in the Mid-1980's. By Donn A Reimund, Nora L Brooks, and Paul D Velde Agriculture and Rural Economics Division, Economic Research Service, U.S. Department of Agriculture Agricultural Economic Report No. 548

#### Abstract

The number of U.S. farms with sales above a quarter million dollars increased by nea  $\frac{1}{2}$  times over the last decade, but about half the gain was due to inflation. This report presents the dimensions of change in the farm sector for a number of variables (income, wealth, ownership, organization, and concentration of production) adjusted for inflation to document the actual change between 1974 and 1982. It also presents economic profiles of typical farms by region for major commodities.

Keywords Farm size, distribution, tyne of farm, commodity concentration, Gini indexes, Lorenz distributions

#### **Preface**

This report is the eighth annual report to the Congress on the status of the family farm. These reports are prepared at 1 submitted to the Congress annually in accordance with Section 102 of the Food and Agriculture Act of 1977 and Section 1608 of the Agriculture and Food. Act of 1981. The authors gratefully acknowledge the contribution of Lynn Tate for his work in compiling the data, estimating Gini Indexes, and plotting distribution curves for the fection on commodity concentration. David Harrington developed the conceptival basis for the distribution curves.

The primary source of data for this report is the Census of Agriculture, using data from the 1974, 1978, and 1982 Summary and State volumes, and the 1979 Farm Finance Survey Regional data for 1982 are sums of the States as regional figures were not published. Additional data on income, assets, and financial status were obtained from *Economic Indicators of the Farm Sector Income and Balance Sheet Statistics*, 1983. Data on the ownership of land are from a landownership survey conducted by USD<sub>1</sub>, in 1978.

#### **Summary**

The dimensions of change in the U.S. farm sector over the last decade tend to be exaggerated because they are generally reported without adjusting for inflation. When the changes are recalculated in constant dollars, a truer picture emerges showing substantially less actual change.

For example, the censuses of agriculture document that the number of farms with sales above \$250,000 grew by 143 percent between 1974 and 1982 in current dollars. Yet, more than half of that increase was due solely to inflationary increases in commodity prices.

Likewise, the number of farms with sales of less than \$10,000 declined by 9 percent in current dollars, but just 1.5 percent in constant dollars.

Similar calculations also show little change in the level of concentration of prorhiction and acres harvested between 1974 and 1982. The top 10 percent of farms producing corn, for example, accounted for 42 percent of production in 1974 and 37 percent in 1982. Only orchard crops and vegetables, among urop commodities, and beef cows and hogs, among livestock commodities, showed the largest farms to be gaining market share. For all other farm commodities, the level of concentration either declined slightly or was steady, refuting the supposition that U.S. agricultural production is becoming more and more concentrated in the hands of a small number of very large producers.

This report compares several farm characteristics of the mid-1980's with those of a decade earlier to document it e real amount of change. It looks at sources and levels of farm operator income and wealth, factor ownership and control, the organization of farm enterprises, and resource use. Farms are stratified into five groups based on their farm income:

- Rural residence farms, less than \$10,000 in gross farm sales.
- Small family farms, gross farm sales ranging from \$10,000-\$39,999.
- Family farms, gross farm sales ranging from \$40,000-\$249.999.
- Large family farms, gross farm sales of \$250,000-\$499,999.
- Very large farms, gross farm sales of \$500,000 or more.

income and Wealth. Off-farm income has exceeded farm income in the farm sector since about 1967. But the relative importance of off-farm income is inversely related to farm size. It makes up virtually the entire operator family income on small family farms and rural residence farms, but only 4-5 percent of total operator family income on the very large farms. Net fann income is concentrated in the larger size groups. Very large farms and large family farms, the two largest size groups, together accrued from two-thirds to over four-fifths of net farm income in the early 1980's, but constitute less than 4 percent

of all farms. Because of off-farm income, total operator family income is more equally distributed across farm size groups than net farm income is.

Farm operators' net worth, after peaking in 1981, declined each year thereafter. Farmers' net worth was \$816.4 billion on January 1, 1984, 10 percent bekiw the January 1981 peak. The decline in net worth resulted from asset value declines of over 5 percent between January 1981 and January 1984, and an increase of 18 percent in farm debt over the same penicd. Debt/asset ratios increased for all farm size groups between 1980 and 1984.

Ownership and Organization. Individuals, partnerships, and corporations whose primary occupation or business is farming owned half of the farmland in the United States in 1982. An additional 14 percent was owned by individual, partnership, and corporate farm operators whose principal occupation was something other than farming. The remaining 36 percent was owned by nonfarmers. Sole proprietors and husband-wife combinations made up 88 percent of farmland owners and owned over 70 percent of the land. The largest 1 percent of farmland owners owned 32 percent of farmland and the top 5 percent of owners owned 53 percent. Farmland ownership is most concentrated in the Pacific and Mountain regions and least concentrated in the Lake States and Corn Belt.

Production. Larger farms usually generate a higher proportion of their sales from the more intensive horticultural crops and fed cattle, while smaller family farms produce more grains, nonfed cattle, dairy products, and hogs. Horticultural crops contribute about one-fifth of very large farms' total sales. Grains contribute 30-40 percent of the total sales for the large family, family, and small family farms. Cattle is the most important commodity for both very large and rural residence farms; fed cattle account for over 80 percent of very large farm cattle sales. Large farms almost invariably have higher crop yields than smaller farms.

Technology affects the organization of the farm sector by contributing to increased levels of specialization and higher capital requirements. This in turn increases production and financial risks, which leads to the use of management practices similar to those of the industrial sector and vertical coordination in an effort to reduce risk. Strategies to reduce risk favor large farms, and consequently have contributed to the growth of very large farms and to the decline of family and small ramily farms.

There is a wide variation in the intensity of resource use across farm size groups, with the most intense use of resources being made by very large farms and the least intense use made by rural residence farms. Two measures — percent of cropland harvested and receipts per dollar of total assets — both show a strong positive relationship between farm size and the intensity of resource use.

## The U.S. Farm Sector in the Mid-1980's

Donn A. Reimund Nora L. Brooks Paul D. Velde

#### Introduction

The structure of agriculture has undergone numerous changes in the past few decades. The tendency toward a bimodal distribution of farms became more pronounced as medium-sized operations either shrank to become manageable part-time businesses or grew to become viable full-time commercial ventures. This report looks at the distribution of farms across five sales classes. Profiles were developed for each size of farm to study its composition, the type of commodities it produced, its sources of income and wealth, and its ownership and nontrol of factors of production.

We examined concentration of production for several commodities from two different perspectives. In the first, we used Gini indexes and distribution curves to see if the concentration of production changed for specific commodities as a result of changes in something other than the price level. The second looks at production of the specified commodity by type of ferm. This analysis is done on both a national and regional level—the regions used are those where the greatest concentration of production of the commodity is found.

We used five classes of farins:

- Rural residence farms—less than \$10,000 gross farm sales.
- Small family farms—gross farm sales of \$10,000-\$39,999.
- Family farms-gross farm sales of \$40,000-\$249,999.
- Large family farms—gross farm sales of \$250,000-\$499,999.
- Very large farms—gross farm sales of \$500,000 or more.

Rural recidence farms (less than \$10,000 in gross farm sales per year) account for nearly half of all farms in the United States (tables 1 and 2). They account for about a third of all farms in the North Central States, about half in the Northeast and the West, and nearly two-thirds of all farms in the South. The farming activity here is normally an avocation or hobby. They serve primarily as residences for individuals with nonfarm occupations or retirement income who are attracted to rural living. Although the average net farm income on such places has been consistently negative by our accounting procedures over the past several years, the average total income of the operators has been equal to or above the national median family income in most years.

Small family farms (\$10,000-\$39,999 in gross farm sales per year) include slightly more than a fifth "all farms in the United States (tables 1 and 2). The heavies, concentration of these farms is in the North Central States, where they are slightly over a fourth of all farms. These small farms are frequently part-time operations whose proprietors combine off-farm earnings with farm income to achieve a setisfactory income level. Average net farm income on these farm 3 has been very low over the past several years, with off-farm income being the major source of income for the Everage operator. This group of farmers had the !owest average total income of all farm operators in the first half of the 1980's.

Family farms (\$40,000-\$249,999 in gross farm sales per year) constitute a fourth of all farms in the United States (tables 1 and 2). They range from 14 percent of all farms in the South to just over a third of all North Central farms. Family farms are usually full-time commercial ventures, and have traditionally been the primary source of income for their operators. However, declining net farm incomes since the early 1980's have caused many family farmers to rely more on off-farm sources to maintain an adequate income level. In recent years, from 30 to over 50 percent of family farmers' total income has been from off-farm sources.

Large family farms (\$250,000-\$499,999 in gross farm sales per year) constitute only 2.6 percent of all U.S. farms (tables 1 and 2), ranging from 2 percent of all Southern farms to 3.7 percent of Western farms. These larger farms are chiefly family-controlled businesses. However, they are more likely to have multiple operators than farms in the next smaller size group. Nearly 40 percent of the large family farms are organized as partnerships and family corporations, compared with just under 20 percent of the next smaller group, family farms. Large family farms generate substantial net farm incomes, averaging over \$60,000 in recent years. Off-farm income, although substantial, contributes less than 20 percent of total operator income for this size group.

Very large farms (more than \$500,000 in gross farm sales per year) account for 1.2 percent of all farms in the United States (tables 1 and 2). Their regional concentration is about 1 percent of all farms in all regions except the West, where they are 3.3 percent of all farms. Most of these farms have multiple operators. Over 53 percent of them are operated as either partnerships or family corporations. An additional 6 percent

The astimates in table 2 are derived from annual farm number estimates made by the Statistical Reporting Service and differ slightly from the Census of Agriculture farm counts shown in table 1. Regional farm number data are available only from the Census.

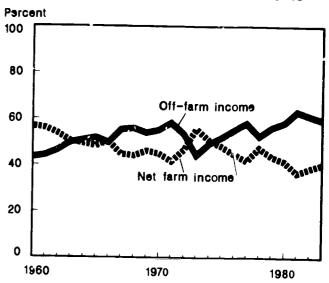

are operated as nonfamily corporations, over two-thirds of which have 10 or fewer shareholders. Detailed data for nonfamily corporate farms are shown in appendix tables 11-14. Net farm income on these very large farms averaged over \$580,000 over the past several years, and contributed about 95 percent to total operator income.

#### Income Sources

Farmers receive income from both farm and off-farm sources. Off-farm income is now the primary source of farm sector income, having increased from 43 percent of the sector's total income in 1960 to 60 percent in 1983 (fig. 1). Net farm income includes net cash income from farming operations, Government payments, and noncash income such as the implicit rental value of the operator's dwelling and the value of farm-produced commodities consumed on the farm. Off-farm income is all income derived from sources off the farm, and includes wages and professional income, income from off-farm investments, and income from retirement and disability pensions.

Net farm Income is concentrated in the larger farm size groups. Very large farms and large family farms the two largest size groups, together generated between two-thirds and four-fifths of total net farm income in the early 1980's (table 3). Family size farms received 25-35 percent of total net farm income in the early 1980's. The percentage of total net farm income received by small family farms ranged from a high of just over 3 percent in 1983 to -1 percent in 1981. Net farm income for rural residence farms was negative throughout the early 1980's.

Net Farm and Off-farm Income as Percent of Total Farm Sector Income

Off-farm Income is inversely related to farm size. It contributes only a small proportion (4-5 percent) of total operator family income on very large farms (table 4). However, on small family and rural residence farms, virtually all farm family income is derived from off-farm sources.

Over two-thirds of off-farm income earned by farm operators and members of their families was from wages and salaries in 1979, the latest year for which such data are available (table 5). Income from nonfarm businesses and professions contributed another 4 percent of off-farm income, raising the total percentage of off-farm income earned from nonfarm work to over three-fourths for all farm operator families.

There is a relationship between farm size and the source of off-farm income. The importance of nonfarm wages and salaries as an income source increases as farm size decreases, as does retirement and disability income. Investment income, which is slightly more important than wages and salaries for large-scale farm operator families, declines with farm size and

accounts for lass than 8 percent of off-farm income for rural residence farm families (table 5).

Faim operator family income is more equally distributed across farm size than is net farm income because of the high proportion of total income earned from off-farm sources by operators of smaller farms. Although well over two-thirds of aggregate net farm income accrued to the two top farm size groups during the early 1980's, they earned less than one-third of aggregate total income from farm and off-farm sources. At the other end of the farm size scale, rural residence farms had integrative net farm income throughout the early 1980's, but earned slightly more than a third of aggregate total income (table 6).

Income per farm — net farm, off-farm, and total family income — for 1980-83 by farm size is shown in table 7. Total family income for all size groups was above the national median family income in every year. That was due, however, to the influence of the very high total incomes of the large and very large farms. Those two size groups together account for only 4 percent of all farms and the three smaller size groups did not fare nearly as well in relation to national median family income. Operator families on family size farms had total incomes above the national median in 2 of the 4 years. Operators of small family farm had the lowest total family incomes throughout the period.

<sup>&</sup>lt;sup>2</sup>Includes income from public assistance, welfare, unemployment compensation, annuities, alimony, contributions from other persons, and other sources.

#### Sources of Wealth

Farm operators' wealth, after peaking in 1981, declined each year through 1983. Farm operators' net worth (including farm households) stood at \$816.4 billion on January 1, 1984, 10 percent below the January 1981 peak of \$907.8 billion. The decline in net worth was the result of lower asset values (down more than 5 percent between January 1981 and January 1984) and an increase in farm debt (18 percent).

#### **Assets**

Farm operators' assets consist of physical farm assets, farm financial assets, and nonfarm assets. Physical farm assets include farm real estate, livestock and poultry, machinery and motor vehicles, stored crops, and household goods. Financial farm assets include currency, dept sits, and investments in farmer cooperatives. Nonfarm asset include nonfarm property, investments in nonfarm businesses, and equipment for nonfarm uses.

The value of physical farm assets, which constitute about 95 percent of farm assets, reached a peak of \$432,000 per farm in 1981 following a steep increase during the inflationary 1970's. By 1984, the per farm value of physical farm assets had fallen by 6 percent from the 1983 peak to \$414,000 (table 8). The value of farm real estate, which is about four-fifths of the value of all physical farm assets, declined by nearly 8 percent nationally between 1981 and 1984, from \$340,000 to \$323,000 per farm. The decline in farm real estato values, however, was not equally distributed across regions. The heaviest losses were in the Corn Belt and Central Plains States, where declines exceeding 40 percent were recorded between 1981 and 1985, the Lake States, and the South (fig. 2).

The value of financial farm assets increased by more than a fifth, from \$18,000 to \$22,000 per farm between 1980 and 1984 (table 9). Investments in cooperatives, with a growth of nearly 36 percent, accounted for most of the increase. Investments in cooperatives increased from 51 percent of financial farm assets in 1980 to 56 percent in 1984.

Although investments in cooperatives make up over half of total financial farm assets, their relative importance is much greater for large farms than small. Very large farms held about nine-tenths of their financial assets in investments in cooperatives in 1984; rural residence farms held only about 12 percent. Very large farms, just over 1 percant of all farms, hold nearly 20 percent of the total value of larmer investments in cooperatives. Smaller farms hold most of their financial assets in deposits and currency, which made up 55 percent of the financial assets of small family size farms in 1984 and nearly 75 percent of the financial assets of rural residence farms.

There is no data series on farmers' nonfarm assets. The only available data are for 1979, from the 1979 Census Farm

Finance Survey. 1 According to this source, farmers owned \$36.3 billion of nonfarm assets, slightly less than 6 percent of their total assets (table 10). Nonfarm assets were more important to the Lalance sheets of small farm operators than to operators of larger farms. Over 10 percent of total assets of rural residence farm operators were nonfarm assets, compared with 3 percent for very large farm operators. Rural residence farms owned about 40 percent of all nonfarm assets owned by farm operators in 1979.

#### Liabilities

Liabilities and debts of al! farmers as of January 1384 totaled \$214.7 billion, 20.8 percent of total farm assets. On a per farm basis, liabilities and debt totaled \$91,000 (table 11). Since 1980, farm liabilities have risen nearly 30 percent from \$165.8 billion. About \$5 percent of total farm debt was owed by family size farms in 1984, the same percentage as in 1980. Very large farms owed 18 percent of the total 1984 farm debt, large family farms 15 percent, small family farms 12 percent, and rural residence farms 9 percent.

Real estate debt accounted for slightly over half of total farm debt in 1984. Real estate debt by farm size ranged from 65 percent of total farm debt for rural residence farms to 42 percent for very large farms. Real estate debt was over half of total farm debt for all size groups except very large farms.

#### **Net Worth**

Farm operators' net worth per farm, after peaking at \$373,000 in 1981, declined by \$28,000 by 1984, and was \$2,000 lower than in 1980 (table 12). The decline in equity was the result of lower asset values and rising farm debts between 1981 and 1984.

Figure 2

The decline in equity was steepest for larger farms. Operators' equity per farm fell by 15 percent for large family farms between 1981 and 1984, and 12.6 percent for very large farms. At the other end of the scale, operators' equity fell by less than 4 percent for rural residence farms and less than 6 percent for small family farms. Operators' equity on family size farms fell by 7.6 percent.

Debt/asset ratios increased substantially during the early 1980's. The average debt/asset ratio for all farms rose from 16.5 percent in 1980 to 20.8 percent in 1934 (table 13). The two largest farm size groups had the biggest increases in their debt/asset ratios

Dsclining asset values since 1981 have meant that many farmers suffered sizable capital losses during the early eighties in contrast to the substantial capital gains of the middle and late seventies, when farm asset values were appreciating rapidly. Real capital gains (defined as the change in the real value of physical farm assets after subtracting real net investment plus the changes in the real values of currency, demand deposits, and farm debts as a percent of operators' equity) averaged nearly 10 percent per year from 1973-79. From 1980-83, real capital losses averaged over 5 percent of

op rators' equity per year for the farm sector. These losses, combined with very low returns to equity from current income, resulted in negative total real returns to equity for the farm sector during the early eighties.

The combination of low current returns and declining farm asset values caused cash flow shortfalls for many farmers. Farmers

with debt/asset ratios of 40 percent or higher are likely to be under serious financial stress. Large family and family size farms with high debt/asset ratios (40 percent or higher) are the most likely to have financial difficulties. Very large farms, which tend to operate a higher proportion of leased assets than smaller farms, have a smaller proportion of their costs committed to asset ownership, and are often able to operate with higher debt/asset ratios. Small family and rural residence farms rely more on off-farm income, which can be used to meet farm operating costs and debt repayment. The number of farms with debt/asset ratios of 40 percent or higher and their cash surplus or shortfall is show. In table 14.

#### Factor Ownership and Control

Land is the major factor of production in farming, accounting for about three-fourths of the sector's total asset value. Consequently, who owns or controls the land is of paramount importance to the development and productivity of agriculture. This section examines landownership and tenure patterns.

7

<sup>&</sup>lt;sup>2</sup>Preliminary

#### **Farm Operator Tenure**

The Census of Agnoulture reported 932 million acres of land in farms in 1982, excluding abnormal farms. Of this, 598 million acres (64 percent of the total) were owned by the operator. Farm operators rented or leased (in) from others 382 million acres (41 percent of land in farms), and rented or leased (out) to other farmers 48 million acres or 5 percent of land in farms (table 15).

Regionally, the highest proportion of operator owned land, 77 percent, was in the Northeast; the Western States had the iowest proportion of operator-owned land at 62 percent. The highest proportion of land rented in by the operator (42 percent) was in the North Central region, and the lowest proportion of land rented in (25 percent) was in the Northeast. The Northeast also had the lowest proportion of land rented or leased to others by farm operators (nearly 3 percent of land in farms), while the South had the highest proportion (6 percent) of land rented out.

Rural residence farms had the highest proportions of whied land and land rented out, and the lowest ratio of land rented

in. Large family farms had the lowest ratios of owned land and land rented out, and the highest ratio of land rented in.

The ratio of land resided by farm operators to total land in farms has increased slightly over the past several years, from 37.5 percent in 1969 to 41 percent in 1982. During the same period, the percentage of tenant farmers declined from 12.9 to 11.6 percent of all far in operators, and the percentage of farmland operated by tenant farmers declined from 15.6 to 11.9 percent. The percentage of farmland operated by part-owner operations increased from 33.5 percent in 1969 to 55.8 percent in 1542, while the land operated by fuil-owner farmers decreased from 50.8 to 32.3 percent.

Part-owner farms tend to be larger than either full-owner or tenant farms. Part-owner farms averaged 794 acres in 1982, compared with 428 ac. for tenant farms and 227 acres for full-owner farms. Part-owner farms, about 30 percent of all faims, are nearly 60 percent of tarms in the two largest farm size groups, and about half of the farms in the family size group. By contrast, part-owner farms constitute about 30 percent of the small family farm group and 15 percent of the

rural residence farms. Over half of the small family farms and over three-fourths of the rural residence farms are operated by full owners.

The proportion of rented or leased farmland operated by part owners has been increasing for several decades. In 1982, part owners operated over 70 percent of rented farmland. The increasing proportion of land operated by part owners is due to the limited availability of farmland to purchase, and to capital limitations. Many farmers have chosen to lease rather than purchase additional land as a means of expanding the size of their operations. In addition, some tenant farmers have purchased some land and thus been reclassified to part-owners.

#### Farmland Owner-hip

Individuals, partnerships, and corpc. ations whose primary occupation or business is farming owned half of the farmland in the United States, according to the 1982 Census of Agriculture. An additional 14.1 percent was owned by individual: partnerships, or corporations whose principal occupation was something other than farming. The remaining 35.9 percent of farmland was owned by nonfarmers.

Only limited information is available on the identification of nonfarmer owners of farmland. The best data are from the 1378 Landownership Survey conducted by the Department of Agriculture.<sup>2</sup> According to that survey, farmers made up 25 percent of noncorporate owners of farmland and owned 56.4 percent of privately held noncorporate farmland. Retired persons, 24 percent of noncorporate farmland. The remaining noncorporate farmland was owned by persons in white collar, blue collar, and other occupations (fig. 3). A large proportion of the retired farmland cwners are probably retired farmers who rent their land to heirs or other farmers to provide a retirement income.

<sup>&</sup>lt;sup>3</sup>Debt/asset ratios between 70 and 100 percent in the 1984 operating year.

<sup>&</sup>lt;sup>4</sup>Debt/asset ratios over 100 percent in the 1984 operating year.

Farmland ownership by form of business organization is largely by individuals and families. Sole proprietors and husband-wife combinations made up 82 percent of the owners, and owned over 70 percent of the land. Family partnerships and family corporations together owned nearly 19 percent of the farmland. Nonfamily corporations owned 4 percent of the farmland, and nonfamily partnerships owned 2 percent of the farmland (fig. 4).

Ownership of formland is concentrated in the hands of relatively few. The top 1 percent of owners held 32 percent of farmland and the top 5 percent owned 53 percent of the farmland. Farmland ownership is most concentrated in the Pacific and Mountain regions and least concentrated in the Lake States and Corn Belt (fig. 5).

#### Farm Organization

The manner in which farms are organized to conduct their business both affects and is affected by the scale of the farming operation and the types of commodities produced. A large commercial farm, for example, will probably have its farming activities organized differently than a small part-time family farm or a rural residence farm where farming is often a secondary activity rather than the operator's primary source of livelihood. There are no direct measures of farm organization, for each farm is a unique situation and this uniqueness is reflected in its organization. But several variables can be measured to indicate variations in farm organization. Here, we examine a few of these variables: farming enterprises, technology, yields, and intensity of resource use

#### Farm Enterprises

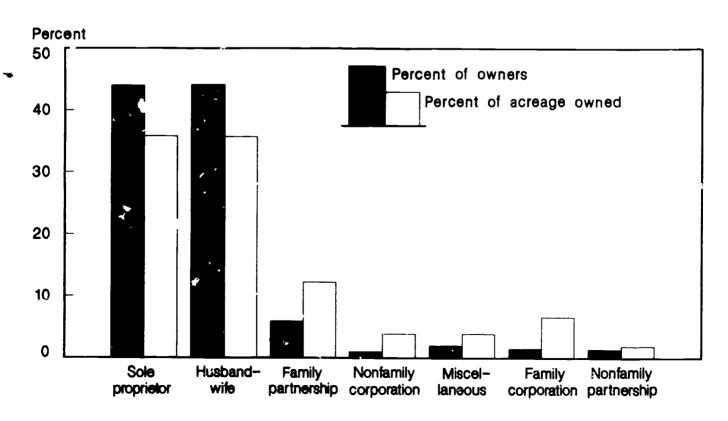

Or 9 way of looking at the relationship between farm size and organization is to examine the relative importance of various commodities for different farm size groups. Table 16 shows the aggregate contribution of major classes of commodities to the total sales of each farm size group. These data point out the differences in enterprise orientation among the size groups. Intensive horticultural crops — vagetables, fruits and nuts, and nursery products -- contribute about one-fifth of the total commodity sales of very large farms, about a tenth for large family farms, and 5-6 percent for family, small family, and rural residence farms. In contrast, grains are the most important commodities for large family, family, and small family farms, contributing from over 30 to nearly 40 percent of total commodity sales. Cattle is the most important commodity for both very large and rural residence farms. However, fed cattle constitute over 80 percent of the total cattle sales from very large (arms, but only 10 percent of rural residence sales of farm cattle. In general, larger farms generate a higher proportion of their sales from the more intensive horticultural crops and fed cattle, while smaller family farms are more likely to produce grains, nonfed cattle, dairy products, and hogs.

Table 17 shows the percentage of sales from each commodity accounted for by the different farm size groups. Very large farms dominate the sales of cotton, horticultural crops, poultry, and fed cattle. Family size farms dominate the sales of grains, tobacco, hay and field seeds, dairy products, and hogs. Rural residence farms account for a significant share (about 10 percent) of tobacco, hay ano field seeds, and sheep sales.

#### **Technology**

Technological innovations in agriculture over the past few decades fall into two basic classes, those that raise yields and those that reduce labor. Yield-increasing innovations include improved, higher yielding crop varieties and improved livestock and poultry strains that have faster growth rates or better feed conversion ratios.<sup>3</sup> Labor-reducing innovations involve the substitution of mechanical power or chemicals for labor, and include improved and larger machinery, mechanized harvesting of several crops, mechanized or automated livestock- and

Business Organization of Landowners, 1978

<sup>&</sup>lt;sup>3</sup>Feed conversion ratio is a measure of the relationship of feed consumed by livestock or pou'try and the amount of product — finished weight of animal, eggs, milk. It is expressed as the pounds of feed consumed per unit of output

poultry-feeding systems, and chemical herbicides that reduce the labor required to control weeds and pests.

These technological innovations have had a large impact on the organization of the farm sector. They have generally reduced costs, increased output, and increased size. This has allowed fewer farmers to produce a larger output at lower costs now than was possible a few years ago. Consequently, technology has been a key factor in the decline in farm numbers and increased farm size.

Technological innovation has also affected farm organization by contributing to increased levels of commodity specialization and by raising the capital requirements for farming. This, in turn, has increased both the production and financial risks of farmers. To cope with these risks, new strategies and institutions for risk aversion have developed. These strategies include vertical coordination, including heavy reliance on forward contracting and pricing, less control of product flows and characteristics by farm producers and more control by processors and marketers, and the use of financial management practices similar to those employed in the industrial sector of the economy. These risk aversion strategies have favored larger producers over small and medium-sized farms, and consequently have contributed to the growth of very large farms and the decline in the numbers of family size and small farms.

Early adopters of new technological innovations benefited through lower production costs and higher output compared with farmers using older technologies. Their higher returns encouraged them to expand the scale of their farming operations. However, as the new methods become used by more and more farmers, commodity prices fall to levels commensu-

rate with the higher total output and lower production costs associated with the new technologies. Farmers still producing under the old technology are faced with several options: adopt the new technology to operate at a profit; reduce their farming activities to a part-time basis and find off-farm employment to supplement their incomes; continue operating at a loss; or leave farming altogether.

#### **Yields**

Large farms get higher yields (table 18). Why that is so is uncertain but several factors may play a role:

- Large farm operators employ better management and cultural practices than operators of smaller farms.
- Larger farms have better quality resources than smaller farms.
- Larger farms are located in areas better suited to the production of a specific commodity. For example com is produced on larger farms in the Com Belt, where yields are higher, than it is in the South, where yields are lower.

These factors probably contribute to large farras' better yields.

#### Intensity of Resource Use

There is a wide variation in the intensity of resource use by farm size, with the very large farms using resources most intensely and rural residence farms using them least intensely. Two measures, percent of cropland harvested (table 19) and receipts per dollar of total assets, demonstrate that.

Source: Compiled from data in the 1982 Census of Agriculture, U.S. Dept. of Commerce

Very large farms, with receipts of 39 cents per dollar of assets in 1983, had a receipts-to-asset ratio more than twice that of large family farms, with receipts of 18 cents per dollar of assets. Family size farms had 14 cents in receipts for each dollar of assets, small family farms 9 cents, and rural residence farms only 5 cents. Receipts per dollar of assets averaged 15 cents for all farms.

# Concentration of Production and Land Input by Commodity

Changes in the structure of agriculture — a long-term decline in the number of farms, larger average farm size, and increased concentration of agricultural resources and production among larger farms — have raised issues concerning the level of concentration in farming and the continued ability of family farms to compete in markets dominated by large-scale production units. These concerns are illustrated by USDA statistics that show that the proportion of gross item income accruing to very large farms increased from about 20 percent in the mid-1970's to nearly 28 percent in the early 1980's, while their share of net farm income rose from about 25 percent to over 50 percent. These statistics also show that the number of very large farms increased from 0.4 percent of all farms in the mid-1970's to 1 percent in the early 1980's. Census data show that very large farms increased their proportion of product sales from 22 percent of the total value of sales for farms selling more than \$2,500 in 1974 to 33 percent in 1982. The percentage of farmland in such farms increased from 6 percent to 12 percent.

Although these statistics indicate an increased concentration of both production and resources at the aggregate level, they do not indicate the degree to which the level of concentration may have changed for specific commodities during the period. These statistics are also affected by increases in the general price level. The high inflation rate between 1973 and 1980 may have pushed many farms into higher sales classes, even

Table 19 - Intensity of cropland used

Farm size	Cropland harvested, 1982	Cropland in pasture			
	Percent of cropland

Large family	84.0	5.3			
Family	78 8	9 1			
Small family	65 1	9 1			
Rural residence	40 3	46.2			
All farm average	73.3	146			

without real changes in farm size. Because of that, time series comparisons of sales class statistics are faulty. The effect of inflation on farm size is examined in the next section.

This section examines changes in the degree of concentration of production and land used for producing specific agricultural commodities. The methodologies employed in the analysis, Gini index-Lorenz curves and distribution curves, are not influenced by changes in the general price level — in contrast to the nominal measures obtained by comparing changes in farm sales class distribution across time periods.

#### Gini Index-Lorenz Curve Analysis

Lorenz curves are derived by plotting the cumulative percentage of individuals — in this case, farms — against the cumulative percentage of some associated variable — production, or acres, in this analysis. The resulting curve shows how the variable is distributed among all farms. If production were uniformly distributed among farms, the Lorenz curve would be a diagonal line (fig. 6). The degree of concentration of production is measured by the deviation of the curve from the diagonal; the larger the area between the curve and the diagonal the higher the degree of concentration.

The Gini index is calculated as the ratio of the area between the diagonal and the Lorenz curve to the total area under the

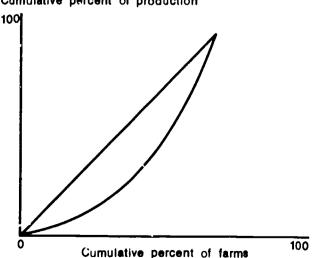

diagonal. The value of the index ranges from zero to one. A value of zero represents a uniform distribution of production across all farms in the above illustration. The closer the value of the index to one, the higher the degree of concentration.

Gini indexes were calculated for selected major commodities for 1974, 1978, and 1982 using Census of Agriculture data (tables 20 and 21). Volume or production was used as the output variable for all crop commodities except orchard crops and vegetables, where value of sales was the output variable. Acres harvested for each crop was the variable used to measure input concentration. For livestock commodities, inventory was used as the concentration variable, except for broilers and hogs where value of sales was used.

To calculate the Gini indexes, the number of farms in each Cer sus sales class producing a specific commodity was calculated as the percentage of all fanns producing that con-modity. These were then arranged from the smallest to the largest sales class and the percentage of production, acres harvested, or other concentration variables accounted for by each sales class was calculated. These percentages were then used to calculate the Gini indexes. The Gini indexes indicate that there was little change in the degree of concentration in the production of agricultural commodities between 1974 and 1978. Only orchard crops and vegetables, among the crop commodities, had a sizable increase in the Gini indexes for their output measure. The index for concentration of acreage harvested was either stable or declined slightly for all other crops. Among livestock commodities, concentration increased for beef cows and hogs. For other livestock commodities, the degree of concentration was virtually unchanged.

Figure 6
Hypothetical Lorenz Curve

Cumulative percent of production

For each crop, we calculated both concentration of output and concentration of harvested acres. In every case, the concentration of output was higher, implying a positive correlation between farm size and land productivity. A number of factors could account for this relationship: larger farms may have higher quality land, use their resources more intensively, use more productive technology, or employ better management and cultural practices.

#### **Distribution Curve Analysis**

Distribution curves snow how variables are distributed across the farm population. They differ from Gini indexes in that the percentage of a variable accounted for by a given percentage of the population can be read directly from the graph.

Figures 7 through 16 are distribution curves for crops showing the distribution of farms by sales class plotted with the distributions of production and acreage harvested for 1974, 1978, and 1982. The distribution curves for livestock commodities, figures 17 through 23, show the percentage distribution of farms and either inventory or value of sales. Companson of the charts

for each commodity across years reveals changes in the distribution of production and acres harvested over the time period. The charts may be read either from the "le is than" scale on the left to determine the percentage of production and acreage accounted for by a given percentage of the smallest farms, or from the "greater than" scale on the right to determine the production and acreage percentages accounted for by a given percentage of the largest farms.

The top 10 percent of farms producing com, for example, accounted for about 42 percent of production on 35 percent of harvested acres in 1974 (fig. 7). The bottom 20 percent of com-producing farms produced about 2 percent of the crop on a little over 2 percent of the harvested acres. In 1982, the top 10 percent of farms producing com accounted for about 37 percent of the crop on 33 percent of the acreage, while the

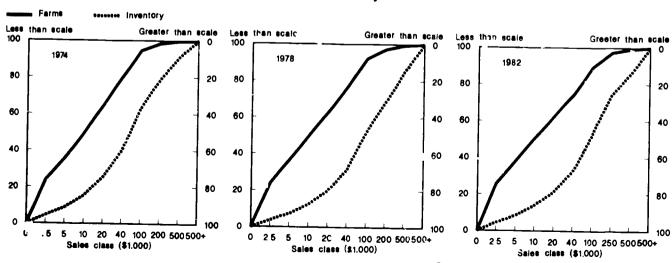

bottom 20 percent produced about 1 percent of the crop on 2 percent of the harvested acres.

The proportion of production and acreage harvested for most crops accounted for by the top 10 percent of farms changed very 'ittle between 1974 and 1982. The same situation was true for the distribution of inventory (or value of sales) for most livestock commodities. Therefore, there were no major shifts of agricultural production and resource use to very large farms. Although there was a substantial increase in the numer of very large farms as measured by changes in census sales class data, both the stability of Gini indexes and the relatively cable percentages of production and acres harvested by the 'cp 10 percent of farms for most major commodities refute the contention that U.S. agriculture is becoming concentrated in the hands of a small number of very large producers.

#### **Changes Over Time**

This section examines changes in the farm sector since 1974. Census of Agriculture data for 1974, 1978, and 1982 are used to trace changes in several of the variables that are important measures of the structure of the farm sector. Structural change variables are examined in both nominal (current collars) and real (1982 dollars) terms to evaluate the extent to which the changes of the past decade were actual physical changes in the structure of agriculture or illusory changes caused by the high inflation rates from the midseventies through the early eighties.

#### **Nominal Changes**

Changes in the published statistics measuring the structure of the farm sector show an increased concentration of both farm assets and production in the larger farm sizes. Although the nurrier of very large and large family farms is still only a small percentage of the total number of farms, their rate of increase between 1974 and 1982 was greater than that of other farm size groups hable 22). The number of very large farms rose by 144 parcent during this period; the number of large family farms rose by the same proportion. In contrast, the number of family farms rose by 24 percent, the number of small family farms dropped by 20 percent, and the number of rural residence farms decreased by 9 percent between 1974 and 1982.

However, the number of rural residence farms increased by 2 percent from 1978-82.

The proportion of farmland hald by the large and very large farms nearly doubled from 1974-82, while the share of land held by family size farms inc. eased slightly (table 23). The amount of land in family size farms declined slightly between 1978 and 1982, although their proportion of farmland remained about the same. The proportion of land held by small family farms and rural residence farms declined from 1974-82. However, from 1978-82 the share of land held by rural residence farms stabilized.

Changes in the proportion of the value of land and buildings held by the various farm size groups paralleled the changes in acreage shares. The proportion of total value held by the two largest farm size groups about doubled from 1974-82 (table 24). Family size farms' share of value of land and buildings increased from 1974-78, but 'ell between 1978 and 1982. The share of value of land and buildings held by small family farms fell thre ighout the entire period, and the share held by rural residence farms decreased between 1974 and 1978, then remained about stable from 1978-82.

Nominal changes in the distribution of sales by farm size between 1974 and 1982 showed an increasing degree of concentration in the two largest classes of farms between 1974

and 1982, and a decline in the proportion of total sales accounted for by the smaller farm size groups (table 25). The two largest size groups increased their share of nominal sales receipts from about a third to nearly half of total farm commodity sales. The percentage of sales accounted for by the two smallest farm size groups fell by about half from 1974-82.

#### Real Changes

To evaluate the impact of inflation on the distribution of farms, commodity sales, and farm assets among farm size groups, he farm counts for 1974 and 1978 were redistributed on the busis of 1982 constant prices. The procedure used was to adjust the 1974 and 1978 value of sales for each farmincluded in the Census of Agriculture for those years to the 1982 price

levels. All farms were then counted into 1982 constant dollar size groups as indicated by their adjusted value of sales. The sales value of crop commodities was adjusted by the index of prices received for all crops; and the index of prices received for livestock and livestock products was used to adjust the sales value of livestock commodities.

Constant dollar farm size distribution. The 1974, 1978, and 1982 distributions of farms among 1982 constant dollar size groups are shown in table 26. Compared with nominal farm size group data in table 21, the increase in the number of very large farms and large family farms, while still sizeable, was considerably lower than the nominal increase. At the other end of the farm size scale, the number of rural residence farms

Excludes abnormal farms.

was quite stable between 1974 and 1982. The 1982 constant dollar rural residence size group declined by fewer than 16,000 compared with the nearly 107,000 drop in rural residences based on nominal dollar groupings. The magnitude of the decline in small family farms was about the same for both the nominal farm size group and the 1982 constant dollar farm size group. The number of family size farms, which had a nominal increase of 107,000, was rather stable when expressed in 1982 constant dollars, increasing by less than 22,000 farms between 1974 and 1982.

The percentage changes in the farm size groups between 1974 and 1932 are shown in table 27 for both nominal and constant dollar size groups. These data indicate that inflation betwoen 1974 and 1982 did indeed have a significant impact on the size distribution of farms. Over half of the increase in the number of farms in the two largest farm size groups can be attributed to farms being reclassified because of inflation Letween 1974 and 1982. About four-fifths of the increase in family size farms is attributable to inflationary commodity price increases. The percentage change in the number of small family farms was about the same whether measured in nominal or 1982 constant doners, indicating that about as many farms were moved into this size group as moved out because of inflation's effect. About 85 percent of the decline in rural residence farms was inflation induced. When measured in constant dollars, there was only a very slight percentage decline in rural residence farms.

Constant dollar asset distribution. The change in the distribution of land in farms and value of land and buildings among the farm size groups between 1974 and 1982 was less pronounced when measured in constant dollars than whon measured in nominal dollars (tables 24, 25, and 28). However, the constant dollar data still show a substantial shift of farm assets into the two largest size groups. The decrease in the proportion of assets held by the small family and rural residence groups was flatter when measured in constant dollars than when measured in nominal dollars. Family size farms, which showed a slight increase in their proportion of assets under the nominal dollar measure, actually showed a smaller proportion of both land and land buildings with the constant dollar measure.

Constant dollar distribution of sales. The change in the distribution of value of products sold, like the changes in asset distributions, was flatter between 1974 and 1982 when measured in constant dollars than when measured in nominal dollars (table 25 and 29). The rate of increase in the percentage of total sales accounted for by the two largest size groups was lower when the effects of price inflation were discounted, but there was still a substantial increase in the concentration of sales in these size groups. Similarly, the two smallest size groups saw their share of farm sales decline less with the constant dollar measure than with the naminal dollar measure. There was little difference between the two measures in the rate of decrease of sales for family size farms.

#### **Profiles of Farms by Size**

This section describes further the farm sales classes defined earlier. We used five sales classes and compared regions with the national average. The basic structural characteristics addressed are farm numbers and size, asset value, sales, tenure, organization, off-farm work, age, and expenses. We also developed a few operating ratios. Most of the data are from the 1982 Census of Agriculture. Data for off-farm income and total cash expenses are for 1982 and are from Economic Indicators of the Farm Sector: Income and Balance Sheet Statistics, 1983.

#### Rurai Residence Farms

The national composite rural residence farm has 110 acres, with the land and buildings valued at \$115,000. This farm has \$13,000 worth of machinery and generates \$3,300 of sales and \$3,200 of cash operating expenses. It is a sole proprietor-

ship run by a full owner, who is 52 years old and works off the farm 200 or more days per year. Off-farm income data were not available on a State and sales class level; nationally, it was \$19.890.

This farm produces \$29.84 of farm products per acre and has \$29.72 of cash expenses, leaving a return of only 12 cents per acre. That works out to 2.5 ce of sales and cash expenses per dollar of asset value.

Nearly half of all farms in the country are rural residence farms. Most are in the South, but the largest are in the West. Western rural residence farms, however, have a negative return on production, while those in the North Central region have a moderate positive return considerably higher than the national average (table 30).

#### **Small Family Farms**

The composite small family farm has 327 acres, valued at \$244,000. It uses \$32,000 worth of machinery to produce

\$21,000 worth of agricultural products and incurs \$13,000 of cash operating expenses. It is a sole proprietorship fully owned by the operator who is 51 years old. Roughly 39 percent of the operators report no off-farm work, although 30 percent report work more than 20C days off the farm, earning income of \$15,067.

These farms generate about \$64 of sales per acre and \$40 of cash expenses leaving a return of \$24 per acre. Land and buildings are valued at about \$746 per acre, while sales are 7.6 cents per dollar of asset value and cash expenses are 4.7 cents. Roughly 62 cents of every dollar of sales is used for expenses.

About half of the small family farms are in the North Central region; a third are in the South. Small family farms in the West are twice as large as in the other regions, but their per acre land values are much lower. For most of the characteristics studied, the regional rankings from highest to lowest are North Central, South, West, and Northeast. Only the operating ratios deviate from his pattern (table 31).

#### **Family-Size Farms**

The composite family-size farm has 793 acres, valued at \$607,000. It has \$83,000 worth of machinery, produces \$99,000 worth of agricultural products, and incurs \$58,000 of cash operating expenses. Although the operator is only a part owner, the family-size farm is a sole proprietorship. The operator is about 48 years old; most report no off-farm work, but those who do have off-farm incomes of \$10,843.

Each acre on this farm produces \$125 of sales from \$73 of cash expenses, leaving a return of \$52. The land is valued at \$765 per acre. In terms of asset value of this farm, there are 14 cents of sales per dollar of assets and 8 cents of cash expenses. Cash expenses claim 60 cents of each dollar of sales.

Roughly a fourth of all the farms in the Nation are in this category. These farms are well distributed across the country with most in the North Central (59 percent) and the fewest in the West (1 percent). Family-size farms in the West are much

Source Census of Agriculture, 1982

larger than those in other regions, but the value of their land is considerably lower, their production, expenses, and return are much lower, and thus a larger land base is necessary to achieve the volumes reached in the other regions (table 32).

#### **Large Family Farms**

The national composite large family farm has 1,807 acres valued at \$1.5 million. It has \$165,000 worth of machinery, produces \$338,000 of agricultural products, and incurs \$205,000 of cash operating expenses. The operator is the sole proprietor, a part owner, 48 years old, with no off-rarm work. Operators who report off-farm work earn an average of \$13,822.

Sales per acre amount to \$187 with cash expenses of \$113 for a return of about \$74 per acre. Land and buildings on this farm are valued at \$821 per acre. The farm generates 21 cents per dollar of asset value, 12 cents of cash expenses per dollar of asset value, and 61 cents of cash expenses per dollar of sales.

Most of the large family farms are in the North Central region. The largest of these farms, in the West, have almost four times as much land and a higher land value per farm, but the per-acre value of the Western farms is considerably lower than those of other regions. The Western farms also have much higher sales per farm and lower sales per acre than farms in other regions, probably due to their much larger acreage (table 33).

#### **Very Large Farms**

The average very large farm has 3,727 acres valued at about \$900 per acre for a total value of \$3.3 million. It has \$280,000 worth of machinery, produces \$1.5 million in sales, and incurs \$1.1 million in cash operating expenses. Generally, it is a sole propnetorship with a part owner, although there are almost as many corporations. The operator is almost 50 years old and most report no off-farm work; those with off-farm jobs have off-farm income of \$27,040.

The very large farm produces \$413 of sales per acre. Cash expenses run \$291 per acre leaving a return of \$122 per acre.

Source: Census of Agriculture, 1982.

The farm generates 43 cents of sales per dollar of asset value, 30 cents of cash expenses per dollar of asset value, and 70 cents of cash expenses per dullar of sales.

Most of the very large farms are in the West. They have the largest acreages and the highest land values, but because they are so large, they have the lowest per acre land values, sales, cash experses, and returns. An interesting regional deviation in organization is in the Northeast and West where corporations outnumber sole proprietorships (table 34).

#### **All Farms**

This profile is given for comparison purposes between sales classes and regions, and the national average. This kind of profile probabily has limited use for other comparisons.

The average U.S. farm has 4.6 acres valued at \$820 per acre for a per farm value of \$341,000 it uses \$42,000 of machinery, produces \$59,000 worth of agricultural products, and incurs \$38,000 of cash operating expenses. It is a sole propnetorship run by a full-owner operator who is 50 years old. About two-fifths of the operators report no off-farm work, but an almost equal number report more than 200 days of off-farm work with average off-farm income of \$16,416.

This farm produces \$142 of goods per acre and incurs \$91 of cash expenses for a return of \$50. It generates about 15 cents of sales per dollar of asset value, almost 10 cents of cash expenses per dollar of asset value, and 64 cents of cash expenses per dollar of sales.

More than half of the farms are in the South; the largest farms are in the West and the smallest are in the Northeast (table 35).

### Appendix: Regional Profiles of Selected Types of Farms

Profiles of several of the major types of crop and livestock farms are presented to characterize the operation of individual farms in each of the selected regions. Profiles were developed for nine types of farms:

- Cash grain
- Tobacco
- Cotton
- Vegetable
- Fruit and nut
- Field crops

- Dairy
- Poultry
- Livestock other than poultry and dairy

For each of these major types of farms, data are presented for the United States and for selected regions. States included in each of the selected regions are indicated in each of the major types of farm profile tables. The farm profile tables show the value of assets, acreages for crop enterprises, income from major commodity sales, total operating expenses, and other farm characteristics such as form of organization and operating ratios. Complete farm profiles for major types of farms and their selected regions are shown in appendix tables 1-10

#### Cash Grain Farms

A cash grain farm is defined as a farm whose sales of cash grains constitute more than half of total cash receipts. The number of cash grain farms in the United States was 576,400 in 1982 (app. table 1). Nearly half of the cash grain farms were in the Corn Belt. The Corn Belt, Southern Plains, Northern Plains, and Northwest contain about 430,000 or 74 percent of total U.S. cash grain farms.

#### **Tobacco Farms**

A tobacco farm is defined as a farm where sales of tobacco constitute more than half of total cash receipts. The number of tobacco farms in the United States was 131,300 in 1982 (app. table 2). Over half of the tobacco farms were in the South Central region. The selected regions contain about 120,000 (or 92 percent of total U.S.) tobacco farms. The selected regions are the Southeast (fligured tobacco) and South Central (burley tobacco). The States included in these regions are specified in appendix table 2.

#### **Cotton Farms**

A cotton farm is defined as a farm where sales of cotton constitute more than half of total cash receipts. The number of cotton farms in the United States was 21,000 in 1982 (app table 3). Nearly half of the cotton farms were in the High Plains Region. The selected regions contain about 18,000 (85 percent of total U.S.) cotton farms. The selected regions are the Delta. High Plains, and Western States The States included in these regions are specified in appendix table 3.

#### **Vegetable Farms**

Avegetable farm is defined as a farm where sales of vegetables constitute more than half of total cash receipts. The number of vegetable farms in the United States was 30,700 in 1982 (app. table 4). The selected regions contain about 15,000 (48 percent of total U.S.) vegetable farms. The selected regions are the Southern Coast, Pacific Coast, Lake States, and Northeast Coast. The States included in these regions are specified in appendix table 4.

#### Fruit and Nut Farms

A fruit and nut farm is defined as a farm where sales of fruit, nuts, and berries constitute more than half of total cash receipts. The number of fruit and nut farms in the United States was 84,300 in 1982 (app. table 5), nearly half in the Pacific Coast region. The selected regions contain about 69,000 (82 percent of total U.S.) fruit and nut farms. The selected regions are Florida-Texas, Southeast, Pacific Coast, and Northeast. The States in each region are specified in appendix table 5

#### Field Crop Farms

A field crop farm is defined as a farm where sales of field crops (other than cash grains) constitute more than haif of total cash receipts. The number of field crop farms in the United States was 100,609 in 1982 (app. table 6). The selected ragions contain about 32,000 (32 percent of total U.S.) field crop farms.

The selected regions are the Red River Valley, Northwest, Southeast, and Southern Plains The States in these regions are specified in appendix table 6

#### **Dairy Farms**

A oairy farm is defined as a farm where sales of dairy products constitute more than half of total cash receipts. The number of dairy farms in the United States was 164,500 in 1982 (app. table 7). Nearly 40 percent of the dairy farms were in the Lake States. The selected regions contain about 100,000 (60

percent of total U.S.) dairy farms. The selected regions are the Northeast, Lake States, and Southwest. The States included in these regions are specified in appendix \*able 7.

#### **Poultry Farms**

A poultry farm is defined as a farm where sales of poultry and poultry products constitute more than half of cash receipts. The number of poultry farms in the United States was 41,900 in 1982 (app. table 8). Nearly half of the poultry farms were in the Southeast. The selected regions contain about 28,300 (67.5 percent of total U.S.) poultry farms. The selected regions are the Southeast, Delmarva, East North Central, and West North Central. The States included in these regions are specified in appendix table 8.

#### Other Livestock Farms 1

Other livestock farms are defined as a farm where sales of cattle and calves, hogs and pigs, and sheep, lamb, and wool constitute more than half of total cash receipts. The number of other livestock farms in the United States was 905,800 in 1982 (app. table 9). Other livestock farms are distributed widely among regions. The selected regions contain about 406,000 (45 percent of total U.S.) other livestock farms. The

selected regions are the Com Belt and Southern Plains. The States in these regions are specified in appendix table 9.

#### **Summary Comparison of Nine Farm Types**

Previous tabulations centered on describing a typical farm in each of several regions for each of nine commodities. This section presents a summary table showing the U.S. average for all nine types of farms. Nine types of commodities represented 2,056,449 U.S. farms (app. table 10). Farms not included in this study were horticulture, general crop, general livestock, and animal specialty farms. The table gives a cross-commodity comparison of the average U.S. farm for each commodity. These data show assets, crop enterprises, sales, expenses, form of organization, and operating ratios. The focus here is on the operating ratios. The commodity with the lowest cash operating expenses per dollar of sales is tobacco (\$0.37), while the commodity with the highest ratio is poultry (\$1.26).

The ratio of cash operating expenses per dollar of sales tended to be higher for livestock farms which ranged from \$0.69-\$1.26. The crop commodities (cash grains, cotton, vegetable, fruit and nuts, and field crops) all have ratios of cash operating expenses

per dollar of sale3 that range from \$0.44-\$0.55. Operating expenses per doller of assets were similar for cash grains, tobacco, and field crops, where the ratio ranged from \$0.05-\$0.06; cotton and fruit and nut farms were the same with a ratio of \$0.08; vegetable and livestock other than poultry and dairy (LOPD) have a ratio of \$C This ratio was higher for Jairy (\$0.19) and much higher f. poultry (\$1.25). Note that the poultry ratios of cash operating expenses per dollar of sale and cash operating expenses per dollar of asset were the same. A wide difference between these ratios existed for all other commodities in this study. A third ratio, sales per dollar of assets, fcr cash grains, tobacco, cotton, orchards, field crops, and LOPD, were within the range of \$0 12-\$0.16. The ratio for dairy (\$0.27) was nearly double that for most of the other commodities, and for poultry was over seven times the ratio for most crops. Poultry was the only commodity with negative cash returns in 1982. Negative cash returns or near breakeven cash returns is not uncommon in the poultry industry. The poultry industry is highly competitive and can increase production rapidly in response to higher prices.

N.S. Hog Industry, by Roy N. Van Arsdall and Kenneth E. Nelson AER-511 June 1984 116 pp \$4 50 Order SN 001-000-04408-7 from GPO

" an excellent report presenting a statistical overview of the industry not available in this concise, readable form in any other publication. I believe my colleagues will share my enthusiasm." R. A. Easter, U. of Illinois, Urbana-Champaign.

The hog industry has moved rapidly in the last 30 years from barnyard sideline to mechanized million-dollar operation. This report describes the most prevalent practices used today. Includes confinement production facilities, breeding, feeding regimens, waste management, and more. Charts, photos, and 54 detailed appendix tables.

Factors Affecting U.S. Milk Production, by Boyd M. Buxton. AER-527. March 1985. 28 pp. \$1.75. Order SN: 001-019-00373-1 from GPO.

Measures effects of changes in major economic factors of milk production on the

amount of milk that dairy farmers produce. Major factors affecting milk production include prices farmers receive for milk, input costs of running a dairy farm, profits farmers would receive in alternative farm enterprises, and general economic conditions.

Milk Production: A Four-State Earnings Comparison, by Boyd M. Buxton, Tom McGuckin, Roger Selley, and Gayle Willett. AER-528. February 1985. 48 pp. \$2.25 Order SN: 001-019-00376-6 from GPO.

Compares profits from dairy farming in Minnesoca, Arizona, New Mexico, and Washington. Estimated rate of return in investment in new dairy operations is higher in the Southwest than in Minnesota or Washington, assuming 1981 prices and construct on and operating costs. This difference comes from lower investment required per cow, more milk produced per cow, and higher milk prices in the Southwest

The U.S. Turkey Industry, by Floyd A Lasley, William L Henson, and Harold B Jones AER-525 March 1985 72 pp \$3 00 Order SN 001-019-00385-5 from GPO

Discusses trends in the thriving turkey industry, an industry which skyrocketed from a modest enterprise with a gross farm value of \$270 million in 1950 to a complex agribusiness with a gross farm value of \$1 25 billion in 1982. Turkey is now consumed year round, currently about 10 8 pounds

per capita annually. The further processed product such as turkey rolls, pot pies, and frozen dinners is the fastest growing sector of the industry.

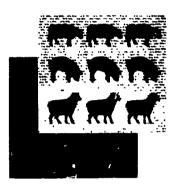

The U.S. Beef Cow-Calf Industry, by Henry C Gilliam Jr AER-515 September 1984 72 pp \$2.75 Order SN 001-019-00352-9 from GPO

This comprehensive look at the U.S. beef cow-calf production industry finds that the number of beef cows fell by about one-fifth between 1975 and 1980 in response to sharp reductions in feeder cattle prices and increases in production costs during the midseventies. Photos and charts illustrate the text

Characteristics of Farmer Cattle Feeding, by Roy N Van Arsdall and Kenneth E Nelson AER-503 August 1983 45 pp \$3.75 Order SN 00.-000-04361-7 from GPO

Now in its second printing, this report examines how the continuing trend toward commercial cattle feeding has reduced the number of farmer cattle feedlots to

113,000 as of 1980, down from 219,000 and 61 percent of the market in 1964 Explains why the number of farmer cattle feeders is expected to decline during the eighties

Livestock and Meat Statistics, 1983. SB-715 December 1984 184 pp \$4 50 Order SN 001-019-00369-3 from GPO

USDA's comprehensive data source for cattle and calves, hogs, poultry, and sheep and lambs includes production and inventories, number red, marketings, slaughter, meat production, prices, per capita consumption, and trade information. Data at your fingertips on foreign trade, storage, and processing of livestock and livestock products—and up to a decade of historical data.
